# EDGE / 5A design rationale: LumaTrail content desk (Case 05)

Generative and Agentic AI for Business, MSc DSAIB 2026–2027. **Julian Fix** (solo).
**Online demo:** https://lumatrail-content-desk.streamlit.app · **Code:** https://github.com/JFxhec/lumatrail-content-desk

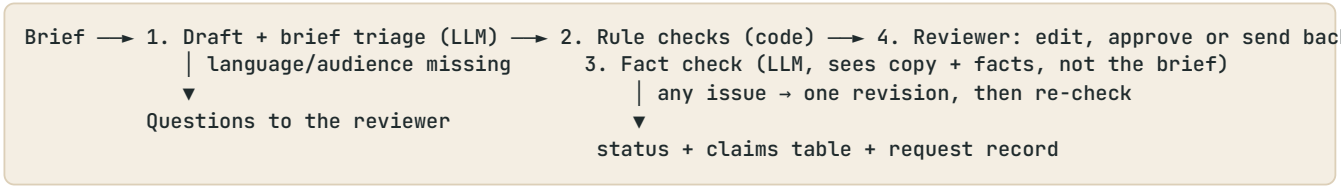

**User.** One LumaTrail marketing reviewer who turns campaign briefs into channel copy and signs it off.

**Problem.** A generic rewrite misses the audience or invents promotions, exaggerated performance and wrong care instructions; the reviewer spends time finding and correcting them. More copy is not the goal: the goal is copy the reviewer can approve with less rework, and a clear view of what is ready and what needs a decision.

**EDGE target.**

- *Efficiency* (primary): fewer factual corrections per approved email and social post. Target: no unsupported claim reaches the reviewer, and every claim arrives with its fact ID, so checking is reading a table, not re-reading the fact sheet.
- *Decisions*: each draft arrives with a status (ready for review / needs attention / needs clarification) and a record of what the brief asked and what was used, qualified or omitted, and why.

**Workflow.**

1. **Draft and triage** (one call). The model lists what the brief asks, decides *used / qualified / omitted* against the fact sheet, writes the copy in the requested language and cites fact IDs for every claim. If the language or audience is missing it writes nothing and asks.
2. **Rule checks** (no model): length limits, wordings the facts rule out (leak-proof, 100% recycled, hot, free delivery, discounts, stock, superlatives, zero impact) in EN/FR/DE/ES, 60% recycled share, output language.
3. **Independent fact check** (reflection pattern): a second call sees only the copy and the facts, so it cannot be talked into a claim by the brief.
4. **One bounded revision** if anything fails, then the checks run again. Remaining issues are shown, not hidden.
5. **Human review.** Editable copy with live rule checks; approval is disabled while a check fails; every decision is logged (`outputs/review_log.jsonl`) with time spent and whether the reviewer edited. Nothing is published.

**5A choice: an Application with a fixed-route automation inside.** The task is stable and repeated, and the pain is review, so the value is in a focused review screen with evidence beside the copy. The route is known in advance (draft, check, revise, review), so an *agent* choosing its next step adds variable cost and no benefit; there are no tools to choose between. *Access* or an *Assistant* (a good reusable prompt) is the baseline we test against, and it turns out to be strong on facts (section 3). Patterns used: planning (brief triage), reflection (independent check, one revision). No multi-agent.

**Human responsibilities.** The reviewer answers clarification questions, edits, approves or sends back. The marketing lead owns `data/facts.json`: a requested offer such as free delivery becomes possible only once it is approved and added there. The tool never decides that a claim is acceptable on its own.

**Trade-offs.** Four times the cost and about three times the latency of the baseline (section 3) for the clarification step, the claim-by-claim evidence and the approval gate. Rule checks are cheap and deterministic but only catch listed wordings; the LLM checker catches paraphrases but is itself noisy.
